

# CERVICAL CANCER DETECTION REPORT

## Patient Information

Patient Name: Dhivi  
Patient ID: 008  
Age: 64  
Gender: Female  
Doctor Name: Shalini  
Examination Date: 2026-03-25

## Diagnosis Result

***Detected Stage: Stage 1***

## Clinical Interpretation

In Stage 1 cervical cancer, the malignancy is limited entirely to the cervix without extension into adjacent anatomical structures. This localized growth indicates a slow progression pattern, allowing for effective therapeutic intervention. Patients may experience minimal clinical manifestations, which can delay diagnosis unless routine screening is performed. Cellular abnormalities remain restricted, and there is no evidence of lymphatic or vascular spread. Management typically includes surgical excision or localized therapies aimed at complete tumor removal. The response to treatment is generally excellent, and recurrence rates are low when appropriate care is provided. Regular monitoring and follow-up imaging are recommended to ensure long-term disease-free survival.

## Image Analysis Summary

The uploaded medical image was processed using advanced image preprocessing techniques including noise reduction, grayscale conversion, and feature extraction. The system analyzed structural and textural patterns using a trained machine learning model to classify the cancer stage accurately.

## Medical Recommendation

It is strongly recommended to consult a gynecologist or oncologist for further diagnosis. Additional tests such as biopsy or HPV testing may be required for confirmation.
